# Drainage Area Data For Wisconsin Streams

By E. W. Henrich, U.S. Geological Survey, and  
D. N. Daniel, Wisconsin Department of Natural Resources

---

## ABSTRACT

Drainage areas were determined for more than 7,000 sites in Wisconsin's 11 major river basins, including all named streams draining 5 or more square miles, and all unnamed streams draining 10 or more square miles. Also determined are drainage areas for gaging stations, sewage-treatment plants, dams, major highway crossings, and other sites where discharge measurements or water-quality data are available.

Drainage areas were delineated on U.S. Geological Survey topographic maps. Drainage areas are shown in tabular form under six headings: station number; stream name, rank, and location; township, range, and section; county; type of site; and drainage area. Eleven major-river-basin maps show the location and station number of key sites.

## INTRODUCTION

The purpose of this report is to present drainage-area data for specified sites on Wisconsin streams. The report lists drainage areas at all sites on named streams of at least 5 mi<sup>2</sup> and at all sites on unnamed streams of 10 mi<sup>2</sup> or more. Also, areas have been determined for sewage-treatment plants, dams, major highway crossings, gaging stations, and other sites where discharge measurements or water-quality data are available.

Drainage area is one of the important factors required for planning and design of water-related projects. This report provides uniform, accurately

determined drainage-area data for use in hydrologic investigations, such as low-flow frequency and flood-frequency studies. It makes drainage-area data readily available in an easy to use format.

Drainage-basin divides were delineated on the latest available U.S. Geological Survey topographic quadrangle maps and procedures recommended by the Subcommittee on Hydrology, Federal Inter-Agency River Basin Committee (written commun., 1951) were used to determine the drainage areas shown in this report. In some cases, the delineated basin divides were corrected to reflect manmade changes not shown on the maps, such as effects of municipal storm-sewer systems and diversion of water for irrigation or agricultural purposes. For streams with headwaters in Minnesota or Michigan, drainage-area data were obtained from the U.S. Geological Survey offices of those States at the most downstream station in the State; the drainage areas were then delineated to the mouths of the streams by the Wisconsin office of the U.S. Geological Survey.

Previous reports by Barry K. Holmstrom (1972), Robert W. Devaul (1973), and Marvin D. Duerk (1974) are included in this report. We would like to acknowledge the contributions of Mark A. Riggle and Bill Shaw (Wisconsin Department of Natural Resources), and of Mark J. Hansen, David J. Henle, and Randall W. Uteck (U.S. Geological Survey). Their efforts were extremely valuable in digitizing and processing of the data in this report.

## EXPLANATION OF DRAINAGE-AREA TABLES

### Station Number

The station number is an 8- or 9-digit number assigned by the U.S. Geological Survey's downstream numbering convention. The first two digits denote the drainage basin ("04" is assigned to the St. Lawrence River Basin and "05" is assigned to Upper Mississippi River Basin). The last six or seven digits, which increase in downstream order, are unique to a specific site.

### Stream Name, Location, and Rank

The stream name is the name shown on the latest edition of U.S. Geological Survey topographic maps. Where unnamed tributaries entered unnamed tributaries, they were named "Tributary" and indented.

The rank of the stream is shown by indentation and indicates the network design of the stream system. The first-ranked stream is always the stream that enters the ocean. The tributary streams are indented two spaces per rank. A typical tributary system is shown and tabulated on figure 1.

### Township, Range, and Section

These three columns locate the site by township, range, and section (quarter-quarter). Almost all of Wisconsin was originally subdivided into survey areas called townships, which are quadrangular areas 6 mi on a side. Townships are numbered northward from the base line at the southern boundary of the State, and each single set constitutes a north-south column. The columns of townships are numbered east and west of a central "principal meridian" and are called ranges (fig. 2).

### County

This column indicates the Wisconsin county the site is located within. Where the site is located in another state that state is listed in parentheses.

### Type of Site

The type of site column refers to hydrologic information available at the site. The coded numbers in the column are explained below:

1. **Gaging stations:** Active and inactive stream-flow and lake stations with continuous records of stage or discharge. Streamflow or lake-stage data are presented in the annual water resources data report.

2. **Low-flow partial-record stations:** Discharge measurements are made during periods of base flow. Estimates of low-flow characteristics at these sites are available in other reports.

3. **Crest-stage partial-record stations:** Peak stages are recorded. Estimates of discharge and flood-frequency characteristics are available in other reports.

4. **Complete partial-record stations:** Low-flow and crest-stage stations are at the same site.

5. **Miscellaneous sites:** Nonperiodic discharge measurements are made for various purposes. Estimates of low-flow characteristics at most of these sites are available in other reports.

6. **Quality-of-water sites:** Water samples are collected for chemical analysis.

7. **Drainage-area sites:** Drainage areas are determined for all named streams of at least 5 mi<sup>2</sup> and of unnamed streams of at least 10 mi<sup>2</sup> at mouth and also for such sites as sewage-treatment plants, major highway crossings, dam, and powerplants.

### Drainage Area

The column under the drainage-area heading lists the drainage area of the site in square miles. In general, the drainage-area figure has been rounded to the nearest 0.01 mi<sup>2</sup> for areas less than 1 mi<sup>2</sup> and to three significant figures for areas more than 1 mi<sup>2</sup>. The drainage area of a stream at a specified location is that area, comprising a topographic basin and enclosed by a topographic divide, from which all direct surface-water runoff drains into. The drainage area for all sites within Wisconsin have been determined by the balanced method, that is, the areas within a quadrangle were either planimetered or digitized to fit the total published area of the quadrangle (Gannett, 1924).

# EXPLANATION

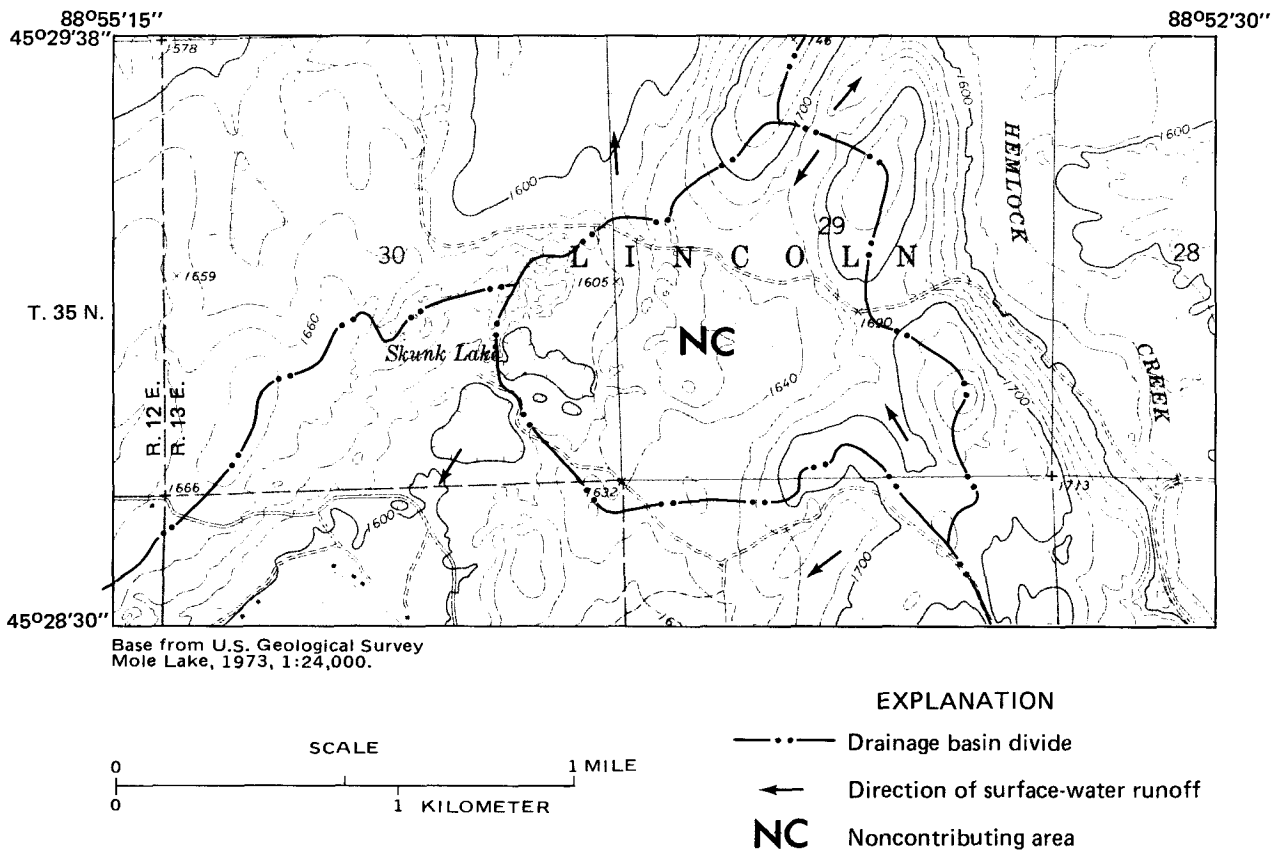

Figure 3. Example of topographic map showing an area that does not contribute surface-water runoff directly to a stream.

## **SIGNIFICANCE OF DRAINAGE-AREA BOUNDARIES**

Not all drainage basins have fixed boundaries. Man's activities and construction along basin divides, such as municipal storm sewers, wetland drainage systems, and irrigation systems, may result in a change of the drainage-basin area. Basin divides are based on topography, which may not coincide with ground-water divides.

No qualification has been made for closed basins--that is, areas that do not contribute directly to surface runoff. In this report, each closed basin is included within the basin to which it is most related hydrologically. Care should be taken in using a drainage-area figure where closed basins are a significant part of the basin area.

The noncontributing area (N.C.), shown on the topographic quad in figure 3, indicates an area where surface-water runoff does not enter a river directly. This area must be added to the most hydrologically similar surrounding area.

## **ACCURACY OF DRAINAGE-AREA DETERMINATION**

The accuracy of the drainage-area data depends on the type of map used, the drainage-basin outline, and the method used to measure the area.

The type of map used affects the accuracy of the drainage-area determination to the greatest degree. The best maps available at the time of the determinations were used. All sites were determined on either 7½- or 15-minute topographic or planimetric quadrangles.

The method used to measure the total area in all basins was the balanced method. This method is the most accurate means of calculating a particular area on topographic quadrangles. The areas within a quadrilateral on 7½- or 15-minute topographic quadrangles were planimetered or digitized and balanced to fit the total published area determined from the Smithsonian Geographical Tables (Federal Interagency River Basin Committee, Subcommittee on Hydrology, 1951, written commun.). The adjustments of planimetered or digitized area to actual area were kept within tolerances of  $\pm 0.5$  percent.

The topographic interpretation used in outlining (delineating) the drainage basin also affects the accuracy. Interpretation involves physically drawing a dividing line between two or more drainage basins on a topographic quadrangle. Basically this means determining which direction the water flows from the highlands to the lowlands. Where the contour intervals are close together, which indicates appreciable relief, determining the divide is fairly easy. However, when the contour interval is widespread as in a flatland area, interpretation becomes more difficult. Figure 4a is an example of contour intervals that are close together. The drainage divide is easy to determine because it follows the hilltops between the drainage basins. Figure 4b is an example of contour intervals that are far apart; thus, the drainage divide could be drawn in either of two locations. The slanted lines between the two different drainage divides show the difference that could result in the drainage area. To minimize this difference in interpretation, several experienced people carefully evaluated the topographic maps and agreed upon divides that could not be clearly defined. Accordingly, the chance for significant error is considered to be small.

## **USE OF TABLES**

The tables contain drainage-area data for more than 7,000 sites on Wisconsin streams. The tables can also be used to determine drainage areas for unlisted sites.

The drainage-area sites are tabulated in downstream order by basin, and some are shown on the basin maps preceding the tables. The State of Wisconsin was subdivided into 11 drainage basins for this report (fig. 5). The area of any listed site may be found by reference to the table after approximate determination of the site number from the appropriate basin map. Drainage area of an unlisted site may be determined by use of the table, with the addition or subtraction of an intervening area to be determined by the user. This method requires that the user employ adequate topographic maps and care in his determination of the intervening area. The intervening area must be added if the site of interest is downstream from a listed station.
